

## WORK & ENERGY DAY 9: POWER

### Warm-Up (3 min): Same Stairs, Different Time

Two students, **Alice** and **Bob**, have the exact same mass (60 kg).

- Alice walks up a flight of stairs with vertical rise  $h = 3.0$  m in **10 s**.
- Bob runs up the same stairs in **2 s**.

1. Who gains more gravitational potential energy,  $\Delta U_g$ ?

2. What quantity is *missing* from your energy analysis that distinguishes Alice and Bob?

Hint: The missing idea is "how fast energy changes." Today we give that idea a name and a formula.

### DEFINING POWER

#### RATE OF ENERGY TRANSFER

**Power ( $P$ )** tells how quickly energy is transferred or work is done.

$$P = \frac{W}{t} = \frac{\Delta E}{t}$$

#### Units:

- SI Unit: **Watt (W)**
- $1 \text{ W} = 1 \text{ J/s}$

#### Conversions:

- 1 horsepower (hp)  $\approx 746 \text{ W}$
- $1 \text{ kW} = 1000 \text{ W}$

### WE DO The Lightbulb

A "60 Watt" lightbulb uses electrical energy to create light (and heat).

**How much energy (in Joules) does it use in 1 minute?**

Knowns:

$$P = \underline{\hspace{2cm}}$$

$$t = \underline{\hspace{2cm}}$$

Calculation:

### Unit Trap: The Kilowatt-hour (kWh)

Your electric bill measures "kWh". Is this **Power** or **Energy**?

$$(\text{Power}) \times (\text{Time}) = (\text{Energy}) \quad \Rightarrow \quad (\text{kW}) \times (\text{hr}) = \text{kWh}$$

So **kWh is a unit of energy** (not power).

## POWER, FORCE, AND VELOCITY

### DERIVATION

Start with the definition:

$$P = \frac{W}{t}$$

Substitute  $W = Fd$ :

$$P = \frac{Fd}{t}$$

Regroup:

$$P = F \left( \frac{d}{t} \right)$$

But  $\frac{d}{t} = v$ , so:

$$P = Fv$$

(More generally:  $P = \vec{F} \cdot \vec{v} = Fv \cos \theta$ .)

### WE DO Car on a Highway

A car is traveling at a constant speed of 30 m/s. Air resistance exerts a force of 600 N against the car.

**How much power must the engine deliver to maintain this speed?**

**Net force idea:** If speed is constant, then  $a = 0$  and **Power:**  $P = Fv$

$$F_{\text{engine}} = F_{\text{air}}$$

Answer: \_\_\_\_\_ W (\_\_\_\_\_ hp)

### YOU DO The Elevator

A 1000 kg elevator is lifted upward at a constant speed of 4.0 m/s. Calculate the power output of the lift motor.

**Force required:** (Draw FBD: tension up, gravity down)

**Power:**  $P = Fv$

$P =$  \_\_\_\_\_ W

$$F_T = \text{_____ N}$$

## SPORTS, CALORIES, AND POWER

### MECHANICAL VS FOOD ENERGY

**Mechanical energy** is the work you do on your body (or on an object).

**Food energy** is chemical energy your body uses to make that work (and lots of heat).

#### Food “Calories”

$$1 \text{ Calorie (food)} = 1 \text{ kcal} = 4184 \text{ J}$$

#### Efficiency (typical)

$$\eta \approx 0.25$$

$$E_{\text{food}} \approx \frac{W_{\text{mech}}}{\eta}$$

A cycling “power meter” reports **mechanical power** (Watts). Your body’s food power is bigger because you are not perfectly efficient.

#### WE DO Bike Power Meter → Calories

A cyclist holds a steady **mechanical** power of  $P_{\text{mech}} = 250 \text{ W}$  for **30 minutes**.

- How much mechanical energy (work) is done?
- Estimate food Calories burned if  $\eta = 0.25$ .

**(a) Mechanical energy:**  $E_{\text{mech}} = Pt$

**(b) Food Calories:**  $E_{\text{food}} = E_{\text{mech}}/\eta$ , then divide by 4184

#### YOU DO Stairs Sprint

A 60 kg runner climbs stairs with vertical rise  $h = 3.0 \text{ m}$  in  $t = 2.0 \text{ s}$ .

- Find the mechanical work gained ( $mgh$ ).
- Find the average mechanical power.
- Estimate food Calories used if  $\eta = 0.25$ .

## HOMEWORK

### 1 Work vs Power

Motor A lifts a 10 kg box 5 m in 2 s. Motor B lifts a 20 kg box 5 m in 4 s.

(a) Which motor did more **work**?  A  B  Same (b) Which used more **power**?  A  B  Same

**Explain your reasoning for power:**

### 2 Hill Climb

A cyclist (mass 70 kg) rides up a hill at a constant speed of 5.0 m/s. The hill is 200 m long and 15 m high. Friction/air resistance is negligible.

- What is the change in gravitational PE?
- How much time does it take to climb the hill?
- Calculate the cyclist's average power output.

### 3 Force and Speed

A jet engine produces 50,000 N of thrust. How much power does it deliver when the plane is flying at 250 m/s?

Answer in MegaWatts (MW): \_\_\_\_\_ MW

### 4 Efficiency (Bonus)

An electric motor uses 500 W of electrical power but only produces 400 W of mechanical lifting power. What happened to the other 100 W?
